How many warning signs do students report?

Students by risk level

Risk Level	Risk Level Count	Cumulative Risk Level %
Low	4,667	62%
Moderate	2,758	99%
High	91	100%
Total	7,516	100%

Average risk score by addiction status

Withdrawal symptoms vs. legal consequences

Legal Consequences	No	Yes	Total
No	69.3%	30.7%	100.0%
Yes	68.7%	31.3%	100.0%
Total	69.1%	30.9%	100.0%

What is associated with reported addiction?

"Top segments" shows groups where addiction is more common. Differences in this dataset are very small. See the Data Quality page.

Data quality check: do these factors predict addiction?

Statistics calculated on all 12,744 raw rows, including the incomplete ones the other pages leave out. Cramér's V below 0.10 means a negligible relationship

Students with and without addiction report the same warning signs

Every relationship is far below a "small" effect

Missing answers per question

5.1%

Every question is missing about 5% of answers

What this means

All 10 factors show a negligible relationship with addiction (Cramér's $V \leq 0.03$). The largest gap is risk-taking behaviour: 33.7% vs 30.0%.

The factors are almost uncorrelated with each other (max $r = 0.02$), each is missing about 5% of answers, and each is answered "Yes" about 30% of the time. Real behavioral data doesn't look like this, so the dataset is likely synthetic.

Treat the other pages as a demonstration of Power BI techniques, not as findings about students.

Statistical evidence: are the answers random?

Each student's risk score compared with a binomial model that treats the 10 answers as independent coin flips ($p = 0.31$)

Observed scores match the model almost exactly (mean 3.07 vs 3.07, variance 2.16 vs 2.14). Real behavioral answers would cluster, giving more students at 0 and 7+. This pattern indicates randomly generated data.
